ABSTRACT: A Planar Inverted-F Antenna for M2M applications is presented. The antenna is located on a rectangular ground plane and operates across both LTE frequency bands (690-960 MHz) and (1710-2690 MHz). The low cost antenna has omni-directional characteristics. The efficiency is better than 80\% in both bands and the average gain is more than -2.1 dBi across the whole frequency range. A parametric study of key geometrical parameters is reported.

Key words: PIFA; LTE; M2M applications.

1. Introduction

Long Term Evolution (LTE) communication systems have been introduced recently, promising to provide greater capacity, throughput rates and better quality of service. For a variety of machine-to-machine (M2M) applications\cite{1} many types of antennas have been reported, such as Planar Inverted-F Antenna (PIFA) antennas\cite{2-5} and monopoles\cite{6-8}. A broadband antenna is required to cover the whole frequency range of the lower and upper band of the LTE standard\cite{8-10}. The performance of any broadband antenna is dependent on its geometrical characteristics and also the size and shape of the ground plane\cite{11, 12} which is a criterion which strongly effects the broadband performance.

In this paper a PIFA structure which operates in the LTE bands (690-960 MHz)/(1710-2690 MHz) is presented for M2M applications. The proposed antenna provides a dual band operation with omnidirectional radiation characteristics, good impedance matching and high efficiency and gain. The effects of the geometrical characteristics of the antenna are studied.

2. PIFA Antenna

Figure 1 shows the geometry of the PIFA antenna, which is located on a ground plane of a single sided FR-4 substrate ($\varepsilon_r=4.3$, thickness=1.5 mm) with dimensions $l=67$ mm $\times$ $h=30$ mm. The top part of the PIFA antenna consists of a thin brass layer (thickness=0.13 mm) with dimensions $l=67$ mm $\times$ $w=33$ mm. The PIFA is fed via a 50 $\Omega$ SMA connector through the ground plane to a feeding strip of 2.7 mm width which is located $a=20.5$ mm from the left edge of the antenna.

The fold-over metallization lengths for the front and back sections are $d=23$ mm and $b=12$ mm respectively. The shorting strip is printed on a thin FR-4 layer (thickness=0.2 mm) and touches the inner part of the FR-4 back side layer (Fig. 1(d)). It connects to the top face of the antenna. The shorting strip width is 7.4 mm and is positioned $s=20$ mm from the edge of the antenna. The antenna was modeled in CST Microwave Studio.

3. Parameter Study

A parametric study of the four key parameters was made. Fig. 3 shows the simulated $S_{11}$ as a function of the length ($l$) of the PIFA antenna. From the graph it is seen that increasing the length of the PIFA antenna shifts the resonances downwards. The proposed value of the length $l$ for the proposed antenna is 67 mm.
Fig. 4 shows the variation of the height \( h \) of the PIFA antenna. As the height of the antenna increases, the impedance matching at the first resonance improves. On the other hand, for the second and third resonance as the height of the antenna increases the impedance matching deteriorates. The optimized value of the height \( h \) for the proposed antenna is 30 mm, providing good matching for both LTE bands.

In Fig. 5 simulated results for the width \( w \) of the antenna are shown. As the value of width \( w \) increases from 12 mm to 40 mm, the low band degrades while the second band matching improves. A suitable value of the width \( w \) of the antenna was chosen to be 33 mm.

Finally, in Fig. 6 the simulated \( S_{11} \) results of the variation of the position \( s \) of the shorting strip are shown. The obtained results clearly show that all resonant frequencies can be controlled (impedance matching and frequency shifting) by varying the parameter \( s \). By considering the results of Fig. 6 the best value of the length \( s \) is 20 mm.

4. Results

The measured and simulated \( S_{11} \) are in good agreement as seen in Fig. 7. The \( S_{11} \) was less than -10 dB over the range 688.5 MHz - 1009.8 MHz, 1736.3 MHz - 2121.5 MHz and 2459 MHz - 2698 MHz giving fractional bandwidths of 40.6%, 20.87% and 9.31%, respectively. The frequency range for \( S_{11} \leq -6 \) dB is 623.5 MHz - 1111.8 MHz and 1621.74 MHz - 3007.04 MHz, (62% and 75%, respectively).
Figure 7  \textit{S}_{11} \text{ of the simulated and measured PIFA antenna.}

In Figs. 8-13 the simulated and measured radiation patterns for \( XZ \), \( YZ \) and \( XY \) planes at the LTE centre frequencies of 825 MHz and 2200 MHz are illustrated.

Figure 8  Measured and simulated \( XY \)-plane patterns at 825 MHz.

At the three planes of 825 MHz it is observed that the Phi (\( \phi \)) component provides good omnidirectional characteristics, which is also observed at the \( XY \)-plane of 2200 MHz for the Theta (\( \theta \)) component. Moreover, at 825 MHz in the \( ZY \)-plane good discrimination between the Phi (\( \phi \)) and Theta (\( \theta \)) component is provided.

The measured maximum gain for the lower and upper band is 4.5 dBi and 6.4 dBi, respectively. The measured gain, averaged over the principle plane cuts (\( XZ \), \( YZ \) and \( XY \)) was -1.1, -1.2, and -2.1 dBi for the low band and -1.4, -1.7 and -1.6 dBi for the high band. The simulated total efficiency is more than 82% and 80% for the first and for the second frequency band, respectively. The maximum total efficiency is 97.5% at 1915.4 MHz.

Figure 9  Measured and simulated \( YZ \)-plane patterns at 825 MHz.

Figure 10  Measured and simulated \( ZX \)-plane patterns at 825 MHz.

Figure 11  Measured and simulated \( XY \)-plane patterns at 2200 MHz.
5. Conclusion

In this paper a parameter study of a dual-band Planar Inverted-F Antenna (PIFA) for the LTE frequency range is presented. The proposed antenna which is suitable for M2M applications provides dual band operation, omnidirectional radiation characteristics, and high total efficiency in both bands and also good gain across the whole frequency range.
