MAKING SENSE OF THE DATA ON IRELAND'S INWARD FDI

(read before the Society, 17 November 2004)

Abstract: Ireland, in employment terms, is the most FDI-intensive economy in the EU. International comparisons of trends and levels of FDI intensity are usually based on balance-of-payments data however, and the international data series on Ireland's inward FDI tell hugely conflicting stories. Such series are published by the IMF, UNCTAD, OECD and Eurostat (with data generally provided either by the CSO or the IDA), while data on US FDI in Ireland are published by the US Bureau of Economic Analysis. The present paper documents these conflicting stories and searches for any underlying consistency through analysis of the items that the various databases include and exclude. FDI stock, flow and sectoral allocation data are explored and trends contrasted with what is known from MNC employment data

Keywords: Foreign Direct Investment; Inward FDI; FDI Stock; FDI Flow

JEL Classification: F21

1. INTRODUCTION

The extent of Ireland's FDI-intensity, in both manufacturing and services, is one of the defining features of the economy. Foreign-owned firms account for almost 50 percent of Irish manufacturing employment, compared to an average figure of 19 percent for the other 11 EU15 member states for which OECD (2001) presents data. The same source reports that a higher-than-average share of Ireland's services sector is also under foreign ownership. Per head of population, UNCTAD data show that the Irish inward FDI stock for 2000 stands at twice the EU average level.

Two different types of data are employed in discussions of FDI. The details given above about Irish manufacturing and services use MNC activity data, which typically yield information on output and/or employment levels in firms under majority foreign ownership. FDI stocks and flows, on the other hand, are generally compiled from balance-of-payments data. Cross-country analyses almost invariably rely on this latter type of data – because cross-country MNC activity data sets are not readily available (other than for US-owned firms) – though activity data are widely agreed to be preferable; Lipsey (2003).¹

FDI in both cases is defined as an investment that involves a lasting interest in an enterprise located in another economy. Its principal distinguishing feature is the significant influence the

¹ Activity data, furthermore, are typically based on the nationality of ultimate ownership of the firms, while balance-of-payments data are based on the immediate source of investment funds. This problem arises with respect to US DI flows to Ireland as a sizeable proportion of DI from the Netherlands in particular is thought to be ultimately from the US; CSO (2003), Desai, Foley and Hines (2002).

foreign investor wields in management. The current international standard for FDI stock and flow data is set out in the 5th edition of the IMF Balance of Payments Manual published in 1993 (henceforth referred to as BPM5) and endorsed by the OECD in 1996 in the 3rd edition of its 'Benchmark Definition of Foreign Direct Investment' (which provides a detailed operational guide to the compilation of FDI data).²

For an investment to be classified as FDI in the balance of payments, the direct investor must own at least 10% of the ordinary shares or voting power of an incorporated enterprise or the equivalent for an unincorporated enterprise.³ Only investments funded through equity, intra-company loans or reinvested earnings are counted as FDI flows. Investments funded through equity or debt issues in the host-economy or on international capital markets, or through equity contributed by local partners in non-wholly owned foreign affiliates, are not included as FDI.⁴

Once a direct investment relationship between entities has been established, all subsequent financial flows are recorded as DI transactions except between MFIs (Monetary Financial Institutions) and other financial intermediaries where DI transactions are confined to those of a permanent capital nature; ECB (2002).

FDI data are available from a number of sources. The IMF, UNCTAD, EUROSTAT and the OECD all publish annual series on FDI flows, and several also publish series on FDI stocks. While most of these are based on data supplied by the CSO, one of the OECD series employs data provided by the IDA. The CSO itself published an FDI series up to 1987 and again from 1998 when it began to provide much more detailed information. FDI stocks and flows relating to US-owned firms are provided by the US Bureau of Economic Analysis.

A major difficulty arises however in that many of these series seem to bear little relationship to each other. Amongst the tasks that the present paper sets itself is to seek to determine why this is so, to search for any underlying consistency that may exist, and to give guidance as to the merits and demerits of the various series. In doing this, it also explores the relationship between these various series and the Forfás and CSO series on foreign-sector manufacturing employment. There is no particular reason to expect a strong or stable relationship between FDI and foreign-firm employment, given that capital-labour ratios will vary across time and across sectors and that FDI is not necessarily closely related to foreign-firm investment.⁵ Similar analyses have been carried out by Lipsey (2003) and UNCTAD (2001) however and some relationship between these types of series has indeed been found.

The paper is organised as follows. The next section explores the various series on FDI inflows. Section 3 looks at the sectoral destinations of FDI inflows. Section 4 explores the series on FDI stocks, and a final section examines the relationship between the FDI and foreign MNC employment series.

² Both organisations have undertaken a number of surveys suggesting that implementation of the recommended methodologies has improved over time, the most recent being the 2001 Survey of Implementation of Methodological Standards for Direct Investment (IMF/OECD 2004).

³ The CSO methodology also reflects particular European Central Bank and Eurostat interpretations of BPM5; CSO (2003).

⁴ Quijano (1990) reports that 81 percent of debt financing of foreign affiliates in the US occurs through US sources of funds. An early study by Stewart (1985) on financing of a panel of foreign firms in Ireland found that bank borrowing (presumed to take place within Ireland) accounted for some 19 percent of gross funds in the 1964 to 1980 period.

⁵ Grubert and Mutti (1991) show that the FDI and foreign-firm investment series on US firms in Canada bear little relationship to each other. Griffith (1999) plots equivalent series for the transport equipment industry in the UK; the FDI series is generally well below the foreign-firm investment series and is substantially more volatile.

2. DATA SERIES ON FDI INFLOWS

Appendix Table 1 lists a number of series on FDI inflows to Ireland, all of which have been converted to US dollars, to facilitate comparison, using contemporary IMF conversion rates.

The values reported by the IMF, UNCTAD and the OECD in one of its series (which we term OECD3) are similar, though the various series are updated at different times. We group these together as the IMF/UNCTAD series.⁶ There are clear breaks in this series in 1990 and 1998, as seen in Figure 1. The figure also depicts the Eurostat1 and Eurostat2 series. Both are seen to lie well above the IMF series in the mid-1990s.⁷

Figure 1: IMF/UNCTAD and Eurostat series on FDI inflows

Figure 2 is drawn to a different scale and graphs the OECD2 series against that of the IMF. OECD2 starts off higher but crosses over in 1990 to become substantially lower.

⁶ The IMF series is from its Balance of Payments Statistics Yearbooks; the UNCTAD series is from its World Investment Reports, and this OECD series (which runs from 1990) is from the 2003 OECD *International Investment Perspectives*. The latter is stated to be sourced from the OECD International Direct Investment database but, as will be seen below, it differs sharply from the OECD2 series reported in some contemporary OECD International Direct Investment Statistics Yearbooks. There is yet another OECD series, OECD1 (not shown), which comes from the country aggregate tables in the 1993 and 2000 editions of the OECD International Direct Investment Statistics Yearbooks, and is largely in line with IMF data to 1998.

⁷ The OECD2 series comes from the IDA and is reported in the country aggregates in the 2001 edition of International Direct Investment Statistics Yearbooks (IDISY) and elsewhere, and is consistent with the sectoral and geographical breakdowns for flows given in other IDISYs. Eurostat 2 comes from various issues of the Eurostat European Union Direct Investment Yearbooks.

Figure 2: IMF/UNCTAD and OECD2 series on FDI Inflows

Figure 3 graphs the two data sets on US FDI into Ireland; one published by the OECD and the other by the US BEA. The BEA values are above the OECD at all times other than 1994, when they dip negative.

Figure 3: Series on US FDI flows to Ireland (BEA and OECD)

2.1 The IMF/UNCTAD Series

We begin with the IMF series. FDI funds, as we have pointed out, comprise equity, intra-company loans and reinvested earnings. The major determinant of the 1990 break in the IMF series was the inclusion of reinvested earnings (RIE) for the first time in that year. Thus the entire series up to 1990 underestimates FDI inflows.

How serious an underestimate might this have been? All the data sources available to us suggest that it would have been substantial.⁸ Figure 4 graphs the three components of FDI inflows in the

⁸ This might particularly be the case in low corporation-tax regimes such as Ireland, as the foreign profits of US MNCs are

US data on Ireland. Table 2 shows that that reinvested earnings, in this series, comprised an average of 80 percent of US FDI inflows to Ireland over the period 1982 to 1998.⁹ A similar pattern is apparent from the IMF series where, in the 1990-1997 period, they accounted for 95 percent of the total. RIE also account for the bulk of FDI inflows in the CSO series from 1998, though a smaller proportion than in the case of the IMF data. We speculate that the latter share may be lower because the CSO series includes substantial IFSC-type flows where RIE may be less important.

Figure 4: Components of US FDI Inflows

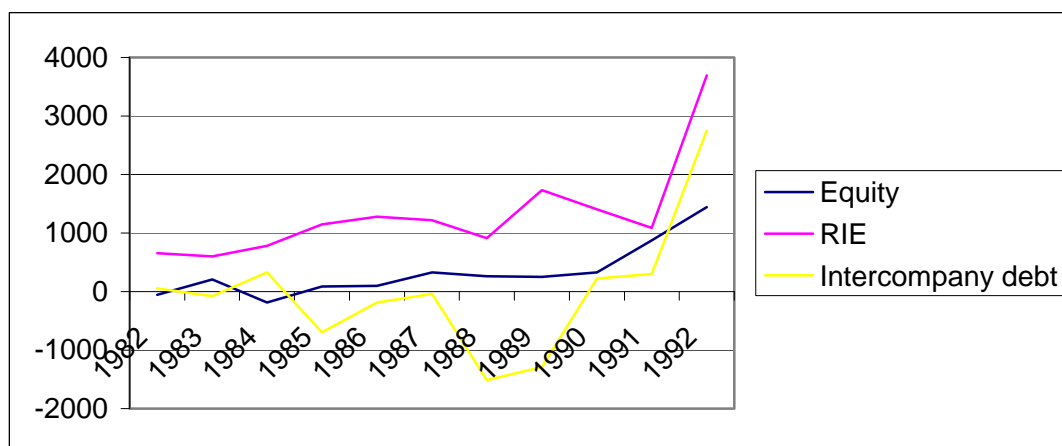

Table 1: Reinvested Earnings as share of total FDI Inflows to Ireland

US BEA data, 1982-1998	.8
IMF data, 1990-1997	.95
CSO data, 1998-2003	.55

If RIE comprise around 80 percent or more of total FDI inflows as the US and IMF data suggest, then including them from 1990 on should increase measured FDI inflows by a factor of at least 5. We see that the IMF series for 1990, when reinvested earnings were included for the first time, actually increases by a factor of around 7. Ireland, it should be noted, was not alone in not recording RIE until this late stage. The 1992 IMF Report on the Measurement of International Capital Flows ('the Godeaux report') indicated that eleven of the industrial countries in its sample

taxed in the United States only when repatriated. Firms with tax-haven profits can therefore earn interest on their residual US tax liability for as long as they defer repatriation of these profits; see e.g. Hines and Rice (1994).

⁹ Prior to 1982, RIE for unincorporated US affiliates were not reported separately and were instead included with other capital flows in the 'equity and intercompany accounts' component of FDI flows; Survey of Current Business (October 1991).

did not compile RIE at that time, though IMF/OECD (1999) reported that six of these had begun to do so by 1997, with further improvements since then; IMF/OECD (2004).¹⁰

Given the importance of RIE in FDI flows, this suggests that great care must be taken in using these FDI series for international comparisons. The caveat becomes even more pressing when it is realised that, for many developed countries, including all of the EU15 other than the Netherlands, at least one component of the FDI flow is not available from the IMF for several years over the course of the 1980s and 1990s; UNCTAD (2000, p.269).

The second major break in the IMF series came in 1998. Changes introduced by the CSO at that time saw Ireland now conform to international conventions, so that all FDI reporting institutions adopted the new series emerging from the CSO. These changes will be discussed in the next subsection. Suffice it to say for the moment that financial service enterprises, particularly enterprises operating from the IFSC, began to be surveyed and the data included in the new series from that time.

The other concurrent change was the introduction of the directional as opposed to the asset/liability presentational method – as recommended by BPM5; CSO (2002) – and, crucially, the fact that gross rather than net directional flows now began to be reported. The asset/liability approach records all outward investments as assets and inward investments as liabilities, whereas the international recommendation is that reverse outward investments (where the direct investment enterprise acquires a financial claim on its direct investor) be netted out of inward investments where the subsidiary owns less than 10% of its direct investor.¹¹ This change would hardly matter in terms of the reported data, as apparently only net flows had been reported up to then, but from 1999 onwards, ‘direct investment flows abroad’ (by Irish investors) were reported separately from ‘direct investment flows into Ireland’ (by foreign investors).¹²

An unresolved issue that arises here however is that while the IMF and UNCTAD were publishing these *net* data on FDI inflows, UNCTAD was also publishing a series on FDI outflows from Ireland. Some details of the two series are given in Table 2, where the inflow data are as in the main IMF/UNCTAD series discussed earlier.

Table 2: Annual average flows; \$ millions.

	FDI Inflows	FDI Outflows
1983-88	99	278
1985-90	192	340
1988-93	787	400

Sources: UNCTAD World Investment Report (1995, 1997, 2000)

¹⁰ The difficulty with RIE is that, since no funds cross borders, data must be collected through enterprise surveys rather than through more traditional balance-of-payments methods. Lack of RIE data may be more significant for some countries than for others. RIE are likely to be higher where FDI has been established for a number of years since the DI enterprise will have acquired the capacity to generate its own funds for reinvestment.

¹¹ Reverse equity investments are generally relatively small but substantial flows and positions can take place under the ‘direct investment – other capital’ category; CSO (2003).

¹² We have been informed that only net figures had been released up to this time because the gross flow data was felt to have been much less reliable.

It would be surprising if there were a net outflow of FDI from Ireland over the 1980s. If the inflow figures are indeed net, then gross inflows can be determined by summing the inflow and outflow data to yield the results in Table 3.

Table 3: A Possible Measure of Gross Relative to Net FDI Inflows suggested by the UNCTAD series.

	Gross Inflow relative to Net Inflow (?)
1983-88	3.81
1985-90	2.77
1988-93	1.51

By way of benchmarking, we can compare these values to the measures of gross relative to net inflows yielded by the new CSO data series for the early years of the new millennium; Table 4.

Table 4: Gross and Net FDI Inflows

	Gross relative to Net FDI Inflows	Gross relative to Net FDI Inflows for non-IFSC-type investments
2001	1.73	4.27
2002	1.41	1.25
2003	1.15	1.1

Source: Balance of International Payments, September 2003 and 2004.

Main Features of the IMF/UNCTAD FDI Inflow Series

Reinvested earnings (RIE) only included from 1990. Earlier FDI inflows likely to have been substantially underestimated.

FDI components other than RIE reported only on a net basis up to 1998. Gross inflows could have been substantially higher.

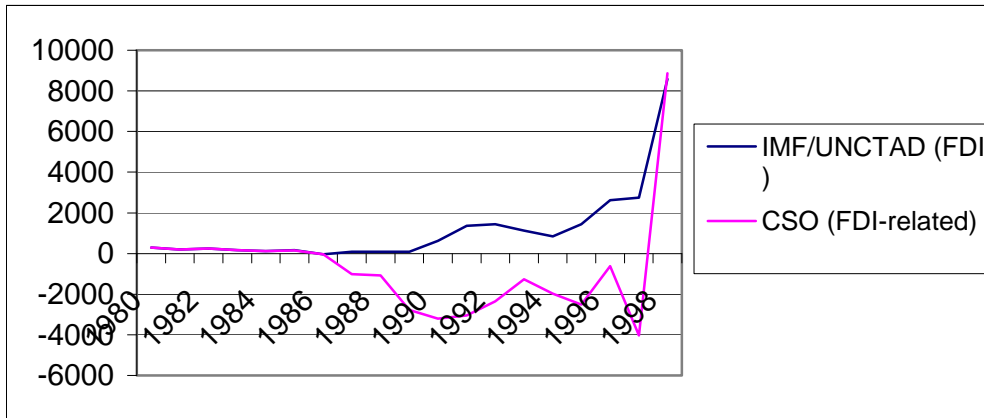

Flows to financial services enterprises included from 1998, resulting in a large jump in the series.

All (non-exclusively-US) sources converge on the CSO figures from then on.

2.2 CSO Series

The CSO published an FDI series up to 1987 which it then provided to the IMF and UNCTAD. In 1987, however, the CSO began to combine direct investment liabilities with 'other private capital', two items which had previously been reported separately. Thus, data for the period 1987-1997 include 'external portfolio investment by Irish residents including that portion financed by domestic foreign currency borrowing; changes in deposits of non-bank resident at certain banks abroad; and any other private capital items not included elsewhere'; CSO (1993). The inclusion of 'other private capital' – an item on which, according to the Statistical Abstracts of Ireland, there had been an outflow in 1972 and in every year from 1975 to 1986 – turned the net figures sharply negative and, by adding portfolio to FDI flows, meant that the CSO abandoned any effort at reporting an FDI series for the period 1987 to 1998. This series is graphed against the IMF/UNCTAD FDI series in Figure 5.

Figure 5: CSO (FDI-related) series graphed against IMF/UNCTAD

The FDI series until 1987 had been calculated via a combination of survey and exchange-control data. The progressive dismantling of exchange controls meant that this data source was drying up, while the quality of response to the surveys was generating growing concerns as to the overall quality of the data.¹³

Be that as it may, the CSO nevertheless continued to provide the relevant FDI data to the IMF. For example, though only beginning to publish a reinvested earnings series in the Balance of Payments in 1995, it reported RIE data to the IMF from 1990 onwards; CSO (1997). It also unbundled Direct Investment from 'other private capital' in its reporting to the IMF, allowing the IMF to continue to publish an FDI series for Ireland.¹⁴

From 1998/1999 the CSO began to publish a new FDI series that embraced financial as well as non-financial FDI sectors. Manufacturing and non-financial service enterprises had been reporting their BOP transactions to the CSO for a number of years, on a sample selection basis. In

¹³ Most EU countries (other than the UK and Ireland) used bank settlement data to estimate FDI flows. After some discussion within the CSO it was decided not to implement this approach. In recent years a number of other EU countries have switched from the bank settlement to the survey method, which Ireland had continued to practice.

¹⁴ It may also have been the source of the UNCTAD estimates of FDI outflows.

1998 however a number of new quarterly surveys were introduced which covered banking, insurance, asset financing, treasury, institutional investment, activities of mutual funds, unit trusts and similar collective investment operations, broking and other service provision. Information collected for all types of enterprises covered transactions with non-residents concerning purchases and sales of services, income flows and acquisitions and disposals of foreign assets or liabilities; CSO (2002).

The new CSO series breaks inflows down into IFSC and non-IFSC types. Non-IFSC inflows are traditional; industrial-type investments whereas, according to Forfás (2002), IFSC-type flows are of quite a different nature, entailing “large movements of capital by parent companies to their treasury, fund management and other IFSC financial subsidiaries, mostly to be reinvested in overseas assets. In this sense, such flows of direct investment into IFSC companies are roughly matched by outward flows of portfolio investment, and have little impact on the real domestic economy”.¹⁵

It is however the total of IFSC and non-IFSC flows that the CSO and the international agencies report as their measure of FDI inflows since 1998.

Main Differences between the CSO and IMF Series

From 1987, Direct Investment liabilities were combined with ‘other private capital’ – including substantial portfolio outflows – so no pure FDI series was published by the CSO between 1987 and 1998.

From 1998 the new CSO series yields data on FDI in financial as well as non-financial sectors. This led to a sharp increase in recorded FDI inflows. While the CSO distinguishes between IFSC-type and non-IFSC-type FDI inflows (with the latter bearing a stronger relationship to the earlier IMF/UNCTAD series), the international organisations now publish the sum of the two series as their measure of inward FDI.

2.3 The OECD2 Series

As mentioned earlier, the OECD2 series starts off higher than the IMF series but crosses over in 1990, eventually becoming substantially lower. Unlike most of the other series, this one for the years 1983-1998 is based on data provided by the IDA rather than the CSO.¹⁶

These IDA data refer to “approved investments” eligible for IDA grant aid. Since grant levels were related more to the level of anticipated employment than to the anticipated level of investment, these “approved investment” values may well have been far removed from the actual

¹⁵ Fund management flows (as is appropriate) are not counted as FDI by the CSO. Flows in support of foreign-owned banks, insurance and investment companies are included as FDI, however, and these generate jobs and physical investment in Ireland, just as is the case with manufacturing-sector FDI. UNCTAD (2004, p. 104) concurs with Forfás however that these flows generate less output and employment: “A good deal of services FDI – notably that in holdings and financial affiliates – involves activities with little value added, employment, sales or investment expenditure on fixed capital”. Forfás reports that most FDI inflows into Ireland from other euro-zone countries went into companies associated with the IFSC.

¹⁶ Many of the numbers reported in this series are obtained from totals in the sectoral and geographical breakdown tables and converted to US\$ using the IMF conversion rates. The data for the years 1994-1997 in OECD2 are also published in US\$m for inflows into Ireland in the aggregated country table in OECD (2001).

level of expenditure invested. It should also be borne in mind that the data refer only to sectors which were grant-aided by the IDA.¹⁷ Furthermore, since aid was directed almost exclusively towards greenfield projects, reinvested earnings would not typically have been included in approved investment levels. Finally, it is important to note that the source of funds for these “approved investments” would not have been taken into account; funds raised on European capital markets would have been included in exactly the same way as equity participation. Thus the OECD/IDA series is not a measure of FDI *per se*.

Why, though, did OECD 2 start off above the IMF series, crossing over in 1990 and eventually falling substantially below it, before the new FDI series produced by the CSO was eventually adopted in the late 1990s?

The IDA figures would have been akin to gross foreign-company greenfield investments while the IMF figures until 1998, as we have seen, are net (with indigenous and foreign-company FDI outflows netted out of foreign-company inflows). This would at least partly explain why the OECD series is above the IMF one until 1990. If the only difference between the IMF and OECD2 (IDA) series for this period were that the former measured net inflows (exclusive of RIE) and the latter measured gross inflows, also exclusive of RIE, then the implied level of FDI outflows to inflows over the period 1983-1989 would have been 2.45, which bears comparison with the results presented earlier. (It needs to be borne in mind however that the IDA series is not a pure FDI series).

From 1990, reinvested earnings are included in the IMF series, which bumps it up dramatically, apparently by a factor of between 5 and 7. It is not surprising, accordingly, that the IMF series dominates from then on, and indeed – in the period 1990 to 1997 inclusive, before IFSC inflows were included – it dominates by an order of magnitude of around 4.

One further point of interest is that, according to the OECD/IDA series, inflows from the US comprised an average of 59 percent of total FDI inflows recorded. This is consistent with the US-firm share of foreign-sector manufacturing employment, which in 1998 stood at 57.3 percent according to the Census of Industrial Production.

Main Features of the OECD2 Inflow Series

Uses data on inward investments eligible for grant aid (provided by IDA rather than CSO). Thus it is not a pure FDI series.

Consistent with the fact that FDI outflows are not netted out in this series as they are in the IMF, inflows exceed those reported by the IMF up to 1990,

From 1990, reinvested earnings included in the IMF series while continuing to be excluded from the OECD2 series, so the former comes to exceed the latter.

Inflows from the US average just fewer than 60 percent of total FDI flows according to this OECD source, which is consistent with the US-firm share of foreign-sector manufacturing employment.

¹⁷ Thus most services sectors would have been excluded, as would SFADCo area companies. Working capital and investments in M&As would also have been excluded, though ‘Ireland is unusual by the standards of most other developed countries in that only a relatively small proportion of inward FDI flows are accounted for by foreign acquisitions of Irish companies (M&As), while an unusually large proportion of inward flows are made up of greenfield investment in new plants, factories and companies’; Forfás (2001).

2.4 The Eurostat Series

Eurostat provide two data series. Eurostat 1 runs from the early 1980s to the early 1990s and excludes RIE while Eurostat 2 yields data for the years 1992 to 1994 and includes RIE.¹⁸ Eurostat 1 yields generally higher numbers than the IMF series while Eurostat 2 yields substantially higher numbers.

Although Eurostat's European Union Direct Investment Yearbooks assert that the data are as reported by the CSO, at least some appears to have been estimated. How might they have been calculated? According to Eurostat (1997), IDA data supplied by the CSO were used to identify foreign countries which had a strong direct investment relationship with Ireland, and Eurostat estimates used for sectoral and geographical breakdowns are then "based on the information available on member state partner countries (plus the USA), combined with a structure of weights based on three declaring countries: the United Kingdom, the Netherlands, and Denmark"; Eurostat (1984-93, p.201) and Eurostat (1996, p.289). RIE, furthermore, are apparently based on a joint Eurostat/OECD questionnaire and are higher than the CSO estimates as reported by the IMF, as Table 5 illustrates.

Table 5: IMF and Eurostat Estimates of Reinvested Earnings, \$m.

	IMF	Eurostat
1992	1336	2248
1993	1024	1600
1994	844	2055

Eurostat produced no FDI data for Ireland for the years 1995-1998, and neither the 1998 or 2000 yearbooks include tables for Ireland or Greece, though data appear to have been estimated to generate overall EU totals. Finally, Eurostat (1995) warns that its figures (for all countries) "should be treated with great caution".

As will be seen in the section on the sectoral allocation of FDI inflows below, the Eurostat estimates include very high values for Financial Intermediation flows while the other data sources largely ignored this sector until 1998. This, we believe, is the main reason why the Eurostat estimates generally come in higher than others for the period up to 1998.

Main Features of the Eurostat Inflow Series

Calculated independently of the CSO until 1998.

RIE also calculated independently.

Series includes estimates for Financial Intermediation flows before the CSO began to survey this sector in 1998. This appears to account for why the values reported are so much higher than those yielded by any of the other data sources.

¹⁸ This series conforms to that of the CSO, IMF etc. from 1998 onwards.

2.5 *The BEA Series on US FDI Inflows*

The main source of data for US FDI stocks and flows into Ireland is the Survey of Current Business (SCB) series compiled by the US Bureau of Economic Analysis (BEA). Country breakdowns of US FDI flows and investment positions are available from 1966.

The BEA uses two types of survey to compile these data. The ‘benchmark surveys’, undertaken every five years, are census surveys covering ‘every US person having a foreign affiliate’ (BEA 1994), though smaller enterprises are exempted from reporting requirements, with the exemption limits having been changed a number of times. These surveys collect BOP and Direct Investment Position (DIP) data, on the one hand, - the type of data we are examining here – and also financial and operating (or activity) data. Smaller sample surveys are undertaken quarterly for the BOP and DIP estimates, and annually for the financial and operating data.

Several changes to the treatment of various items have taken place over the years, though it is not clear what the implications of these might have been for the data on Ireland. One change introduced in 1977 was the rigorous implementation of the rule whereby the direct investor had to have an interest of at least 10% in the company for an investment to be classified as FDI. Prior to 1977, interests of less than 10 percent were also included (i) when another US person held an interest of at least 10% in the same foreign business enterprise, or (ii) when the combined interest of all US persons was at least 50% even if no single person had an interest of at least 10 percent.¹⁹

Another change was that, from June 1990, capital gains and losses associated with currency translation adjustments were removed from the reinvested earnings component and reclassified as valuation adjustments to the Direct Investment Position. Revisions were made back to 1982 (SCB August 1990) and considerably changed the recorded level of aggregate flows. There is no apparent break in the Irish data to reflect this however.

In 1998, intercompany debt transactions and associated interest transactions between parents and affiliates that are financial intermediaries (as opposed to depository institutions) were reclassified from direct to portfolio investment to be consistent with the guidelines in BPM5, though equity capital transactions with these intermediaries have continued to be classified as DI. The data were then revised back as far as 1994.²⁰ Lipsey (2003) suggests that the effect of this change was to reduce net outflows substantially and to reduce volatility. This may have led to a break in the Irish series, though again none is readily apparent.

Comparing the US BEA series to IMF/UNCTAD we see that the US series was consistently higher, and generally substantially so, until 1990, from which time it has almost invariably been lower, and has been consistently lower since 1998. The outcome for the period to 1990 is consistent with two facts: (i) the US series included RIE while the IMF series did not, and (ii) the IMF series netted out outward FDI from indigenous and other firms, while the US series netted out only US firms.

It must also be borne in mind that the US data included FDI in financial concerns which the IMF data would have largely excluded. To take account of the first and last point, we subtract manufacturing RIE from the US total manufacturing FDI inflow figures to see whether these are more closely related to the IMF figures up to 1990.²¹ This indeed, as seen in Table 6 and Figure 6, proves to be the case.

¹⁹ Data prior to 1977 was not revised to reflect this change; Lipsey (2003).

²⁰ It is the revised data that are reported here.

²¹ There was not much inflow into non-financial services sectors up to this point.

Table 6 US Total Manufacturing FDI inflows Excluding RIE

	US BEA: US Man. FDI minus RIE	IMF/UNCTAD: World FDI (excl. RIE)
1982	88	242
1983	22	170
1984	-75	121
1985	84	164
1986	-31	-43
1987	48	89
1988	22	92
1989	201	85
Sum	359	920

Figure 6 US Total Manufacturing FDI inflows Excluding RIE

Between 1990, when the IMF series began to include RIE and 1998 when it took IFSC-type flows into account, the US series excluding values for banking, finance, insurance and real estate, averaged 59 percent of the IMF series, while the US-firm share of foreign-sector manufacturing employment (in 1998) stood at 57.3 percent! The equivalent US series (in this case excluding banking, finance and insurance), between 1999 and 2002, comprised an average of 44 percent of the CSO non-IFSC series over this period.²²

²² The US values for FDI in banking, finance and insurance, on the other hand, comprised an average of between 8 and 13

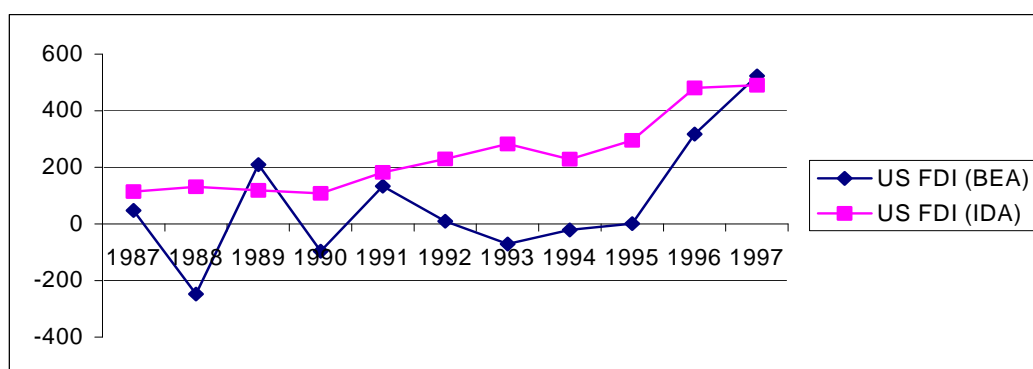

While these last sets of figures may seem broadly compatible, we still need to try to work out the relationship between the OECD (IDA) data on US investments in Ireland and those reported by the US BEA. As the IDA data excludes RIE, we need to exclude these from the BEA data also. Secondly, we need to exclude financial-sector FDI from the BEA data (and presumably some other sectors such as petroleum and wholesale that would not have been grant-aided by the IDA). These series are detailed in Table 7 and the series graphed against each other in Figure 7.

Table 7 Total US FDI less RIE

	US FDI less RIE in sectors other than Banking, Finance, Petrol and Wholesale (BEA)	US FDI (OECD, IDA)
1987	48	114
1988	-248	131
1989	210	118
1990	-96	108
1991	133	182
1992	9	230
1993	-71	283
1994	-21	229
1995	1	295
1996	317	480
1997	523	490
Totals	805	2660

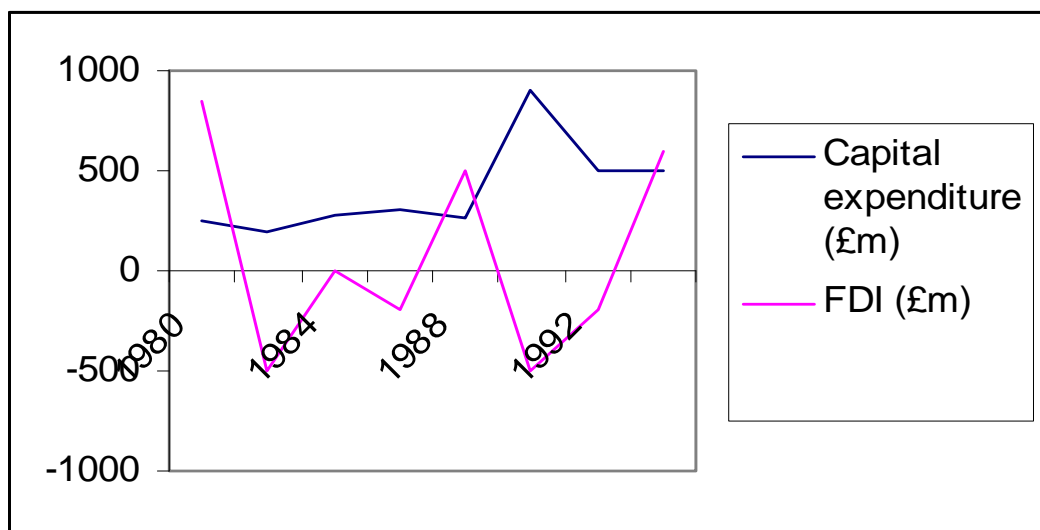

The gap between the two series remains quite substantial, with the BEA series lower and substantially more volatile. As mentioned earlier, Griffith (1999, p.16) plotted broadly equivalent data series on US FDI and US MNC investment in the transport equipment industry in the UK. Figure 8 below replicates her data. In both cases, the FDI series is generally well below the foreign-firm investment series and is substantially more volatile.

Figure 7

percent of the CSO IFSC series, which is consistent with the perception that US FDI is far less dominant within the financial sector than within manufacturing.

Figure 8:

Source: Griffith (1999)

Main Features of the BEA US Inflow Series

US series was consistently higher than IMF until 1990. This is consistent with the fact that the US series included RIE and financial-sector flows over this period while the IMF series excluded them.

US manufacturing FDI excluding RIE over this period came to between one-third and one-half of the IMF series, which is broadly consistent with the employment data.

Between 1990, when the IMF series began to include RIE and 1998 when it took IFSC-type flows into account, the US series excluding values for banking, finance, insurance and real estate, but including RIE, averaged 59 percent of the IMF series, while the US-firm share of foreign-sector manufacturing employment stood at a level very close to this. The equivalent US series, between 1999 and 2002, comprised an average of 44 percent of the CSO non-IFSC series over this period.

The US FDI series was lower and more volatile than the OECD/IDA US MNC investment series. Equivalent findings have been reported for the UK.

3. DATA SERIES ON SECTORAL DISTRIBUTION OF FDI INFLOWS

Three of the international data sources provide information on the sectoral allocation of FDI inflows: Eurostat 1, OECD 2 and the US BEA. Details of the sectoral breakdown in Eurostat 1 – which excludes RIE – are provided in Table 8.

Table 8: Sectoral breakdown of Eurostat 1; US\$ m

	1992	1993	1994
Agriculture & Fishing	0	1	5
Mining & Quarrying	0	-7	-328

Not allocated	38	-18	-125
Total	2830	3109	1878

Source: European Union Direct Investment Yearbook 1996

Notes: minus sign indicates disinvestments.

The main point to be made about this table is the small weight that manufacturing receives, and the extent of the fluctuations in manufacturing-sector FDI. These values fluctuate -\$375 million and \$642 million in the Eurostat1 data. The fluctuations are far less dramatic in any of the other data series we have on manufacturing, as shown in Table 9. Thus we concur with Eurostat's (1995) warning that their figures "should be treated with great caution".

Table 9: Manufacturing Sector FDI, various sources

	1992	1993	1994
Manufacturing (Eurostat 1) excluding RIE	-69	642	-375
IDA values as in OECD 2	377	382	310
IMF series excluding RIE	106	97	-6
US manufacturing excl RIE (BEA)	-36	-253	182

Another source yielding an estimate of the sectoral allocation of FDI inflows is OECD 2, which reports on data provided by the IDA. Unlike the Eurostat source, virtually all of the OECD numbers relate to manufacturing. A selection of these data are reported in Table 10.

Table 10: Sectoral Allocation of FDI inflows

US\$m	1986	1988	1990	1992	1994	1996	1998
Manufacturing of which	234	245	200	364	304	547	548
Food products	63	38	17	31	45	43	53
Textiles and wood products	16	41	25	12	52	91	57
Petroleum, chemicals, rubber& plastic products	44	81	26	66	52	50	43
Metal and mechanical products	112	78	122	240	139	363	396
Other services	3	14	7	12	6	19	34
Unallocated						10	9
Total	250	257	207	376	310	576	591

Sources: OECD International DI Statistics yearbooks 1998 and 1999

This sectoral distribution of FDI inflows is quite consistent with the sectoral distribution of foreign-sector jobs, as shown in Table 11.

Table 11: Sectoral Distribution of FDI inflows and Foreign Sector Employment

	Allocation of FDI inflows, 1986-1998 (%)	Allocation of employment in foreign-owned industry, 1998
Food products	12	11
Textiles and wood products	10	12
Petroleum, chemicals, rubber& plastic products	18	20
Metal and mechanical products	60	57

Source: Employment from Census of Industrial Production (1998)

The US BEA also provides a breakdown of the sectoral destination of FDI inflows, in this case confined to flows from the US, with country details available from 1979. These data are reported in Appendix Table 2. The sectoral classifications are close to but different from the EU NACE classifications; Ruane and Gorg (1996).

There have been name changes for several sectors over the years, none of which are thought to have had significant effects on the values reported, particularly for manufacturing to which we confine our attention here.²³ The sectoral classifications have also changed a number of times over the years, particularly with the shift from SIC to NAICS (the 1997 North American Industrial Classification System), the industry classification system currently used by the US, Canada and Mexico and the system under which the capital outflows for the years 1999-2002 are reported.

Comparing sectoral FDI inflows over the period 1994-2000 with the fairly stable sectoral shares of employment in US-owned firms, we see that three sectors dominate both series: Chemicals, Electronics and a category of diverse 'other' manufacturing sectors.

Table 12: Sectoral Distribution of FDI and US Employment Shares

	Food and kindred products	Chemicals & allied products	primary & fabricated metals	Industrial machinery metals	Electronic & other electric equip	Transport equip	Other man
Share of FDI, 1994-2000	4.14	35.94	1.45	13.62	20.95	0.07	23.78
Share of employment in US-owned firms, 1998	3.76	16.83	3.91	4.15	51.47	1.26	18.63

Source: Employment data from Census of Industrial Production (1998)

Chemicals, however, appears to be strongly overrepresented in the FDI inflow data, with 'other manufacturing' slightly overrepresented and electronics substantially underrepresented. This pattern is at least consistent with the relative capital intensity of these sectors. According to Midelfart et al. (2000), the chemicals sector has a high capital-labour ratio, electronics a low one while the high-foreign-employment sectors in 'other manufacturing' (which are textiles and paper, printing and publishing) have medium-to-high capital-labour ratios. While this explanation appears attractive however, the pattern is nevertheless inconsistent with the findings reported earlier for the FDI-employment ratios in the OECD2/IDA data.

²³ Several changes in manufacturing sector names were made to conform to the nomenclature used in the 1987 Standard Industrial Classification (SIC). Thus 'machinery, except electrical' became 'industrial machinery and equipment', and 'electric and electronic equipment' became 'electronic and other electric equipment' (SCB August 1995).

Findings on the Sectoral Allocation of FDI

- The sectoral allocation data in the Eurostat database are dominated by Financial Services, while fluctuations in manufacturing FDI inflows are very large compared to the other data sources.
- The allocation across manufacturing sectors in the OECD/IDA data is consistent with the employment allocation across these sectors.
- The allocation across manufacturing sectors in the US BEA data is fairly consistent with the sectoral employment allocation.

4. DATA SERIES ON FDI STOCKS

FDI stocks, or 'Direct Investment Positions', measure the value of accumulated flows of FDI. Depending on the valuation methods used, adjustments may occur from year to year not just because of flows but also because of revaluations reflecting changes in exchange rates and prices, as well as reclassifications and corrections.²⁴

UNCTAD presents data on Ireland's FDI stock at 5-yearly intervals for the 1980s and annually from 1992. Huge changes were made to the historic values in UNCTAD (2003) and beyond. The CSO first published International Investment Position (IIP) data in October 2003 with a series beginning in 1998 and plans to continue to publish these data on an annual basis. As with the flow data, direct investment is broken down into equity capital, reinvested earnings and 'other capital' components, and an IFSC/Non-IFSC activity breakdown is also included. (These series are contained in Appendix Table 3).

There is an apparent break in the UNCTAD 1 series in 1995 and a clear one in 2000. We can find no explanation for the surge in the 1995 value, since all the flow data sources show only moderate inflows in 1994. It is clear however that from the year 2000 UNCTAD has adopted CSO figures which include stocks in IFSC activities. In the several years preceding that, UNCTAD values are reasonably close to those reported by the CSO for non-IFSC activities.

UNCTAD (2003) revised its earlier figures very dramatically, raising its estimate of the 1980 stock, for example, by a factor of almost 10. It states that the new estimates of stocks prior to 1999 are generated by subtracting earlier flows from this higher stock value. This seems to us to yield a very misleading picture however, since the new 1999 stock figure adopted from the CSO includes IFSC-type stocks. In recalculating past stocks, UNCTAD has subtracted flows that did not include much IFSC-type FDI from stock values that do, implicitly holding the IFSC stock at its 1999 value and projecting that back into the past, leading to a massive overestimate of historical stocks. Accordingly we use the UNCTAD1 rather than UNCTAD2 series as our benchmark in the discussion below.

Appendix Table 3 also gives estimates of the net accumulated stock of capital that US parents have provided to their foreign affiliates. The direct investment position is the book value of US direct investors' equity in, and net outstanding loans to, their foreign affiliates; SCB (June 1990).

²⁴ See Lipsey (2003) on the various valuation methods used. The CSO position is that stocks should be evaluated on a current cost basis but give examples where this might not be possible; IIP release, December 2002. It goes on to say that 'market valuation where not directly available is generally approximated using one of the following in order of preference: (a) a recent transaction price, (b) directors' valuation, or (c) net asset value'.

Stocks are measured at historical cost as this is the basis used for valuation in company accounting records in the US and so is the only basis on which companies can report data in the direct investment surveys; USDIA 1994 Benchmark Survey, Final Results.²⁵

The table also gives a series for the US FDI stock in manufacturing and services, excluding wholesale, finance and real estate. This is probably close to what is normally thought of as US FDI in Ireland (in that it includes software and IT-enabled services for example). This series started out dominated by manufacturing FDI but from the late 1990s has consisted of equal parts manufacturing and services.

These numbers come in at around 50 percent of the UNCTAD1 values for the total FDI stock in Ireland up to the year 2000, at which time UNCTAD started to include values for the IFSC. From that time on, the US numbers have come in at a somewhat lower proportion of the CSO numbers for the stock of non-IFSC FDI. These findings are reasonably consistent with the employment breakdown between US and other foreign-owned firms. In its December 2003 FDI issue, the CSO published a geographical breakdown of DI positions, which Table 13 below compares with the DIP reported by the US.²⁶ These sets of numbers also turn out to be reasonably close.

**Table 13: Comparison of the CSO and US BEA Direct Investment Positions
(including IFSC-type)**

5. CORRELATIONS BETWEEN FDI STOCKS AND EMPLOYMENT SERIES

We now wish to explore the relationship, if any, between these various FDI stocks series and employment levels in foreign-owned manufacturing firms. These employment data, as compiled by Forfás, are presented in Appendix Table 4.

We first take the (pre-revision) UNCTAD1 series with data points at 1980, 1985, 1990 and 1992-1999, to which we add the CSO non-IFSC figure for 2000. This yields a correlation coefficient of 0.8979 when compared with the foreign-MNC employment series.²⁷

²⁵ Historical costing is widely considered to underestimate the value of investment stocks because it values the asset at its purchase price and so ignores inflation. As a result BEA, since 1991, also uses current-cost and market-value estimates of the overall Direct Investment Position. However country detail continues to be available only on a historical-cost basis.

²⁶ The CSO issue gives breakdowns between equity capital and reinvested earnings (as an aggregate) and 'other capital' but, as the US does not provide these breakdowns, they have not been reported here.

²⁷ The correlation between these series for the 5-year intervals between 1980 and 2000 (the only years for which we have

We next look at the US Direct Investment Position data, which we take from 1973 to 2000, and run it against the Forfás series on employment in US-owned firms. This yields an even higher correlation coefficient of 0.8997.

Note however that the DI Position includes data on US FDI in financial and other services while the Forfás series contains data only on manufacturing employment. Accordingly we isolate the DI position in manufacturing alone, which yields an extremely high correlation coefficient of 0.9653.

Lipsev (2001) reports on a similar examination of the relation between US outward-FDI stock data and measures of US MNC activity across sectors and across locations. He finds that the FDI stocks are quite closely related across countries to absolute changes in affiliate property, plant and equipment (PP&E) and affiliate sales, but much less closely related to affiliate employment. The relationships fall apart completely however when sectoral allocations are examined.

UNCTAD (2001; Annex D) also examines the relationship between FDI stock and MNC activity data for the US BEA data. This study shows a positive correlation between the US outward FDI position and employment abroad by US affiliates. For 1989 the correlation coefficient was 0.882, and for manufacturing alone 0.885. Changes in the outward FDI position and changes in employment (from 1966 to 1989) are much less strongly correlated. UNCTAD finds a correlation coefficient of 0.466 for all industries and 0.407 for manufacturing.

Our next and final step is to examine the correlations between the BEA FDI stock and Forfás employment data at the sectoral level.²⁸ These data are presented in Table 14. The correlations are rather mixed, ranging from 0.09 for Industrial Machinery to 0.89 for Chemicals. It is heartening that the correlations are particularly high in the cases of the two sectors that however for the bulk of US-firm employment: Chemicals and related industries (which account for 19 percent in 2000) and Electronics (which account for 60 percent).

Table 14: Correlations between FDI stock and MNC employment data, by sector; 1979-2000.

Food and kindred products	Chemicals & allied products	Primary & fabricated metals	Industrial machinery metals	Electronic & other electric equip	Transport equip	Other manuf
0.23	0.89	0.18	0.09	0.72	0.39	0.30

Source: Employment data from Forfás.

overlapping data) is higher than when this series is replaced by the revised UNCTAD values.

²⁸ The Forfás employment database differs somewhat from the Census of Industrial Production. Forfás reports the following sectoral allocation of employment in US-owned firms in 1998 (in contrast to the CIP allocation reported in Table 12): Food and related (3.7), Chemicals and related (18.5), Primary and fabricated metals (3.8), Industrial machinery (3.6), Electronics (56.1), Transport Equipment (4.9) and Other Manufacturing (9.4). Forfás provides a much longer data series than the CSO however.

Analysis of the FDI stocks series

- We believe UNCTAD committed a serious error in its 2003 revisions to the historical stock series by subtracting flows that did not include much IFSC-type FDI from stock values that did, leading to a massive overestimate of historical stocks.
- The US FDI stock in manufacturing and services (from the BEA) comes in at around 50 percent of the unrevised UNCTAD1 stock values, which increases our faith in the unrevised UNCTAD figures. These unrevised figures are highly correlated, furthermore, with the foreign-MNC employment data, while the correlation is even higher between the US manufacturing FDI stock and the Forfás data series on employment in US-owned manufacturing firms.
- The correlations between the BEA FDI stock and Forfás employment data at the sectoral level are more mixed, but are particularly high in the cases of the two sectors that for the bulk of US-firm employment: Chemicals and Electronics.

6. CONCLUSIONS

Caveat emptor is the main message to emerge from the present analysis. Use of any of these FDI series for international comparisons (other than those coming from the US BEA) comes with many health warnings. Data for one or other of the three components of FDI was missing for fourteen of the EU15 countries for at least several years in the 1980s and 1990s.

The IMF series on Ireland did not include reinvested earnings until 1990, and we have seen that these generally comprise the bulk of FDI inflows. This largely explains the seven-fold jump in recorded FDI inflows to Ireland in 1990.

The CSO stopped publishing a pure FDI series in 1987 and resumed again only in 1998. The new series includes FDI inflows to financial services, heretofore largely excluded. As this is the series now reported by the international organisations (IMF, UNCTAD etc.) the apparent very sharp increase in FDI inflows when the new data source is introduced is misleading. The new CSO series on non-IFSC-type FDI inflows alone bears a stronger relationship to the earlier IMF/UNCTAD series than does the new total FDI series.

The OECD in one of its FDI series uses IDA data on inward investments eligible for grant aid. Thus it is not a pure FDI series. Up to 1990, inflows exceed those reported by the IMF, which is consistent with the fact that the OECD series is a measure akin to gross MNC investment while the IMF series measures net FDI inflows. From 1990, when reinvested earnings are included in the IMF series (while remaining excluded from the OECD2 series), the former comes to exceed the latter. According to the OECD source, inflows from the US average just under 60 percent of total MNC investments, which is consistent with the US-firm share of foreign-sector manufacturing employment.

The Eurostat Inflow series is calculated independently of the CSO (until 1998) and, unlike any of the other (non-US) series, includes estimates for financial intermediation flows. This appears to account for why the values reported are so much higher than those yielded by any of the other data sources.

The US BEA series on US FDI inflows to Ireland was consistently higher than the IMF series on

total FDI inflows until 1990. This is consistent however with the fact that the US series included RIE and financial-sector flows over this period while the IMF series excluded them. Concentrating on manufacturing and taking account of RIE the relationship between the BEA and IMF series (and the CSO non-IFSC series since 1998) is broadly consistent with the employment data. The US FDI series was lower and more volatile than the US MNC investment series provided by the IDA, furthermore, which is consistent with findings for the UK.

Turning our attention now to the data sources yielding information on sectoral allocation of FDI inflows, the results of the Eurostat database arouse suspicion. Flows are dominated by the financial services sector, on which there appears to have been little survey evidence at that time, while the fluctuations in manufacturing FDI inflows are very large in comparison with the other data sources. By contrast, the FDI allocation across manufacturing sectors in both the OECD/IDA data and the data on US FDI from the BEA is fairly consistent with the allocation of employment across these sectors.

The final set of data we explore concern values for the FDI stock in Ireland. UNCTAD provided a historical series of such values but revised these dramatically in *World Investment Report* (2003). The estimate of the 1980 stock, for example, was raised almost tenfold. We believe a serious error was made in these revisions. In recalculating past stocks, UNCTAD subtracted flows that did not include much IFSC-type FDI from stock values that did, which would have resulted in a massive overestimate of historical stocks.

The US FDI stock in manufacturing and services, from the BEA, comes in at around 50 percent of the UNCTAD1 values for the total FDI stock in Ireland up to the year 1999, which increases our faith in the unrevised UNCTAD figures. These unrevised figures are highly correlated, furthermore, with the foreign-MNC employment data, while the correlation is even higher between the US manufacturing FDI stock and the Forfás data series on employment in US-owned manufacturing firms.

7. RECOMMENDATIONS

The decision of the CSO to provide data series that distinguish between IFSC-type and non-IFSC-type FDI is to be lauded. It only remains for us to suggest some other data series that we would like to see provided. Most econometric treatments of FDI-related issues in Ireland use the Forfás manufacturing employment series that distinguishes between foreign and indigenous industry back to 1973 rather than the much shorter one provided by the CSO (in the Census of Industrial Production). It would be very valuable if the CIP were able to be backdated further in distinguishing between indigenous and foreign industry. Forfás also collects other data of immense interest, relating to R&D expenditures for example. Again, these data would be more valuable for analytical purposes could they be combined with CIP-type data.

Perhaps the most glaring void however relates to the paucity of services-sector data. The recent harmonisation of corporation tax rates across sectors and the growing transnationalisation of services will mean that these sectors are likely to attract a growing share of inward FDI to Ireland. Thus collection of CIP-type data for services, allowing a distinction to be drawn between the characteristics and activities of indigenous and foreign firms, as in manufacturing, will hopefully be on the high-priority list for the CSO.

DISCUSSION

Mr. Michael Connolly: I would like to propose a vote of thanks to the authors of this paper, Frank and Clare. The paper is the product of a substantial investigation into the various data series on inward FDI into Ireland and reflects a sound understanding of the concepts underlying this topic. The authors have shown great tenacity in resolving the many inconsistencies that they identify in the paper. They then proceed to validate these findings or hypotheses through the use of various comparative measures. I would now like to make a few observations on the paper together with some more general comments regarding the interpretation of FDI data.

Data Series

There are essentially two types of data series discussed in this paper, domestic data series, that is to say series produced in Ireland, and mirror data series which are data series compiled elsewhere. The domestic series is composed of the CSO Balance of Payments (BOP), published nationally which is also forwarded to the IMF for their publications and the IDA series of data on investment into grant aided industries. The mirror data is from the Bureau of Economic Analysis (BEA) in the US and Eurostat for earlier years. The CSO BOP is the source for two of the series on flows in Table 1 of the paper i.e. IMF/UNCTAD and CSO while IDA data is used for OECD2 series. These data series are relatively consistent until in 1987 when a decision was taken by CSO to combine FDI data with Portfolio Investment data together with data on holdings of deposits abroad under the heading Private Capital. From 1987 until 1997 this series (CSO) ceases to have any analytical value for FDI purposes. The decision to publish at a higher level of aggregation in 1987 reflects the serious concerns that CSO had regarding data quality due to poor survey response and the decreasing value of exchange controls data. During this same period the IMF/UNCTAD data series continued to be based on net FDI flows which were provided by CSO.

From 1998 onwards we find a general convergence towards the use of CSO data by all International Organisations. The paper examines each of these data series through the entire period and the authors' assessments are difficult to disagree with. Regarding the IDA series we also see the analytical value of the series discussed. However, it is clear that this data series is far from comprehensive or complete and cannot really be considered as an FDI series. As part of this assessment of the domestic data, the authors identify reinvested earnings as a probable cause of the break in series in 1990 of the IMF/UNCTAD series. I want to develop this point about reinvested earnings in a more general way.

Re-invested Earnings (RIE)

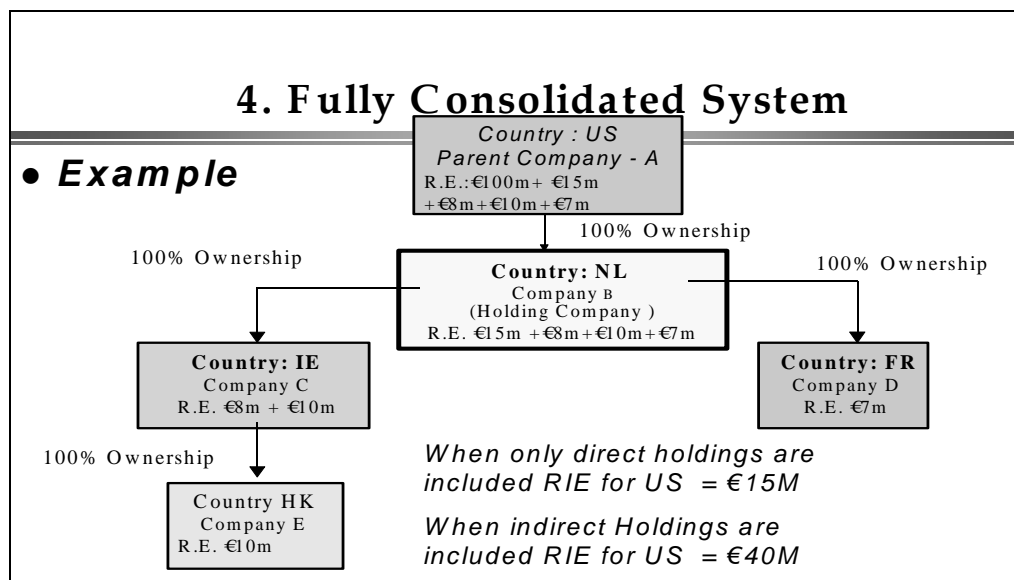

The inclusion of RIE is correctly identified as causing a break in the IMF/UNCTAD flow data series. This resulted from CSO implementation of ESA95 (European System of Accounts) measurement standards for Profits which previously only recorded dividend repatriations. The data was revised in 1995 with back series to 1990. However, we should be clear that all national compilers have still not implemented this change in methodology, at least in the EU. As recently as March 2004 we find the ECB/Eurostat Joint Task Force on FDI (TF-FDI) making the following observations:

“The TF-FDI deems the non-inclusion of reinvested earnings as the most crucial problem in this area. This difficulty seems to be closely connected with the lack of FDI surveys which should be resolved promptly¹...”

The Task Force report goes on to say that collection /compilation methods were in a transitional

¹ Eurostat - ECB March 2004 Foreign Direct Investment Task Force p.108 par. 437

period where some member states had moved from settlement based systems to surveys and direct reporting systems. In many cases, it reported, the features of the collection system used are crucial for the application or non-application of International standards.

A fundamental requirement when compiling reinvested earnings is that a consolidation of RIE takes place at every level in an international group structure by each national FDI compiler i.e. Ireland (IE) consolidates its own earnings of €8m (in this example we assume all profits are retained) from its activities together with those of its subsidiary in Hong Kong - Chinese Protectorate (HK) €10m. These are then recorded as part of the inward direct investment liability flows in the period in question to Netherlands (NL) the owner of the Irish company. Clearly any inconsistency in the statistical treatment by any compiler in any of the countries will cause inconsistencies in the international data series. As mentioned above there are still difficulties being met by countries recording RIE. One proposal to resolve these difficulties is that only RIE from directly held subsidiaries/associates be consolidated. Hence in the above example the reinvested earnings inflow for the US would be reduced from €40m to €15m. It is not clear to me how this proposal will cause anything other than more confusion and asymmetries.

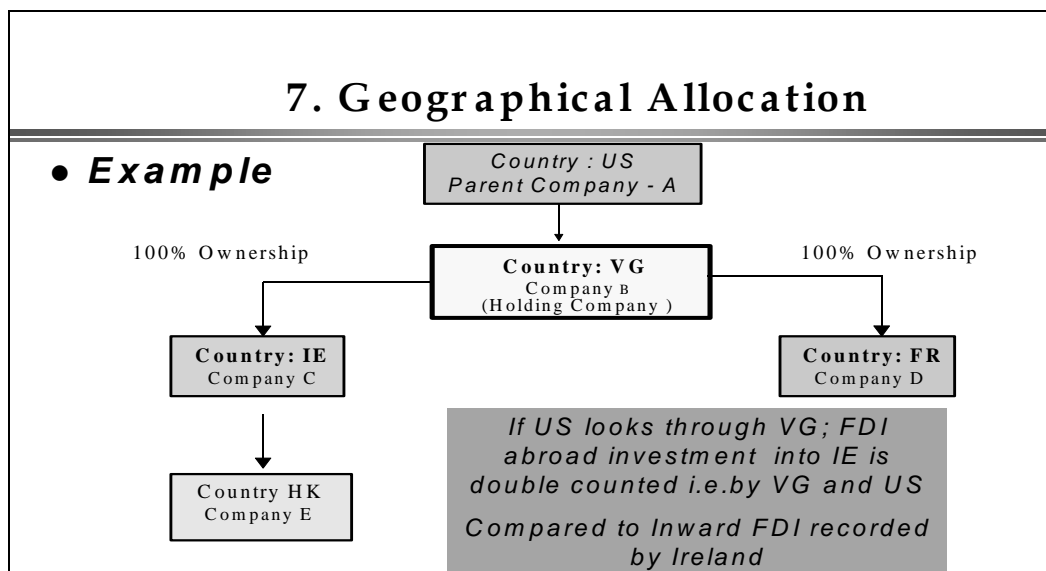

Mirror Data

The paper also makes use of two sources of mirror data from BEA and Eurostat - so called because Irish data on inward investment from the US should be the mirror image of US data on investment abroad into Ireland. The comparisons in the paper using mirror data, on the whole, do not give rise to inconsistencies primarily because there is not a complete Irish compiled series to compare against. Nevertheless, I want to discuss the general use of mirror data and the difficulties that users of these data may encounter. These difficulties are due to the following:

- Geographical allocation;
- Activity sector allocation;
- Directional Principle for Other Capital;
- Misclassification of FDI stocks and flows;
- Special Purpose Entities (SPEs).

Geographical allocation

Direct investment rarely comes directly from the investor country to the host country. Instead it usually is invested via an Offshore company owned by the investor. In this case there may be differences in how the host and investor allocate this investment geographically. The accepted standard for geographical allocation is the *Country of the immediate holder* but in the US, they tend to look through Offshore countries to the country of the ultimate investment.

Accordingly, in the example above, the US would record FDI abroad into Ireland. Ireland would record the FDI in Ireland as coming from the Offshore country. Also, the Offshore country would also record the FDI abroad into Ireland. In this case there is a double count of the investment into Ireland.

Activity Sector Allocation

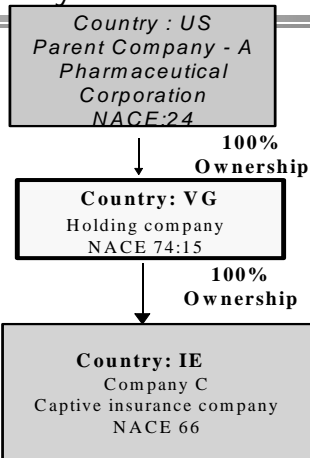

When we consider the activity sector reported in mirror data we have to be aware that the activity sector allocation is based on the sector of the resident company investing abroad. However the company they have created may be involved in entirely different activities. Therefore, a comparison of the mirror data by sector will show inconsistencies.

8. Activity Sector Allocation

• Example

IE Classifies
Company C to
NACE 66 -
Insurance

US Classifies
Company C to
NACE 24 -
Pharmaceutical

In the example we see the consequences for a Pharmaceutical company in US which invests in a captive insurance company in Ireland. Ireland records the activity sector of the Inward FDI as Insurance (NACE² 66) while US records the outward FDI as Pharmaceuticals (NACE 24).

Directional Principle Treatment of FDI –Other Capital

The directional principle is the basis of the recording of FDI data. It differs from the standard assets/liabilities presentation that we see for other elements of the Financial Account of the BOP. The recording of FDI - Other Capital flows and stocks includes all non-equity intra-group transactions between affiliates e.g. loans, trade payables, leases etc. and this data is particularly important for Ireland due to the high concentration of internationally traded financial services companies, especially Treasury companies resident here. Typically the transactions recorded by these companies are between sister companies (affiliates).

² NACE - The statistical classification of economic activities in the European Community

10. DI Other Capital (contd.)

• Loan advanced to a “sister” company :

In the example above the transaction of a loan from company B (the treasury company in Ireland) to company C (the French affiliate) is treated as a transaction in Direct Investment in Ireland, effectively as a disinvestment, because it reduces the level of investment into company B by company A (the owner) by this amount³. However the OECD in the Benchmark Definition of Direct Investment recommends⁴ that this loan be treated as Direct Investment abroad by Ireland into France. The consequence of following the OECD recommendation is a serious inflation of the data for both FDI abroad and FDI in Ireland as illustrated below:

11. Directional Principle - Impact on Irish FDI data

Direct Investment - Other Capital

Direct Investment in Ireland			
OECD Recommended approach		CSO - IMF Approach	
2001 Flows	-6.8	2001 Flows	-9.6
2002 Flows	13.4	2002 Flows	-1.6
Stocks	73.7	Stocks	12.5
Stocks	77.8	Stocks	10.4
Direct Investment Abroad			
2001 Flows	-3.5	2001 Flows	-0.7
2002 Flows	-12.3	2002 Flows	2.6
Stocks	67	Stocks	5.8
Stocks	70.4	Stocks	3
Net Direct Investment			
2001 Flows	-10.3	2001 Flows	-10.3
2002 Flows	1.1	2002 Flows	1.1
Stocks	-6.7	Stocks	-6.7
Stocks	-7.4	Stocks	-7.4

³ See IMF Balance of Payments Compilation Guide - p.332 under the heading: A non-resident direct investor is.....

⁴ OECD Benchmark Definition of Foreign Direct Investment 3rd Edition pp 49-50

Misclassification of FDI stocks and flows

The majority of EU countries are still recording FDI flow data using bank settlement systems and, in the case of intercompany loans, which, as I have said, can form a significant element of overall FDI flows, it can be difficult for these data collection systems to distinguish between intercompany loans and other loans between unrelated third parties. Consequently we could find misclassification in this area of FDI statistics when we use mirror data.

Special Purpose Entities (SPEs)

Company structure has changed dramatically over the past decades and the more straight forward example of the US company creating a subsidiary in Ireland to engage in some manufacturing process is only part of the story regarding inward direct investment in Ireland. Now we find that there has been an unbundling of activities formerly located within the headquarters of a MNC such as Insurance, Treasury, ownership of subsidiaries, shared services etc. These changes partly explain the dramatic increase in inward FDI in Ireland since 1998 although they clearly started earlier than this, probably in the early 1990s. The user of mirror data must be certain that the compilers of the FDI data have systems in place that can record these types of transactions. This in effect means that survey reporting systems have to be in use or otherwise substantial asymmetries will be detected.

Now having discussed the potential pitfalls associated with the use of mirror data I want to return to the changes in our data collection and compilation system from 1998 onwards.

What Changed in 1998?

The CSO data series for FDI and, in general, for BOP statistics improved dramatically in 1998 and we see from the paper that all international organisations are using this data series from 1998 onwards. The reasons for the dramatic improvement are:

The Compliance Framework

- The Statistics Act 1993 – This act gave more wide ranging powers to the CSO for the collection of data and enforcement and also ensured the political independence of the Director General
- European Legislation - The legislation relating to statistical reporting to ECB has created a very exacting compliance framework for CSO. In addition Eurostat has also this year introduced a Regulation governing the provision of Balance of Payments statistics to them.
- IMF Standard Data Dissemination Standards (SDDS) - This has also required subscribing countries to conform to general standards for data dissemination.

Staffing at CSO

The staff numbers have increased from eight in the mid nineties to a current staffing of thirty-seven people.

Increase in Coverage

The number of surveys has increased from three to ten ensuring more comprehensive coverage of the relevant sectors in the economy.

International Developments & Initiatives Underway

Finally, there are currently a number of developments in this area which should be of interest:

The IMF 5th Manual is now in the process of being revised and a number of technical expert groups are discussing many diverse issues, including those I have already mentioned above. The Direct Investment Technical Expert Group (DITEG) was set up under the joint chair of the OECD /IMF and is currently discussing

- Treatment of reinvested earnings
- Basis for the establishment of the Direct Investment relationship -10% or 20% to ensure more consistency with accounting definitions
- The directional principle for FDI statistics and should we revert to an assets/liabilities presentation of this data

- Treatment of Special Purpose Entities (SPEs) whether there is a case for excluding some of these activities from FDI statistics and including them under Portfolio or Other investment.

They are also considering the implications of more standardised reporting which will be possible with the implementation on International Accounting Standards (IAS) on 1 January 2005, at least in the EU.

At IMF there is also the proposal for the establishment of the Co-ordinated Direct Investment Survey which is an initiative to reduce asymmetries in Direct Investment statistics. This survey will have common standards for geographical allocation, valuation and for other issues currently giving rise to international asymmetries in FDI data internationally and should increase the potential for meaningful use of mirror data for the purposes of quality checking national or regional data.

Once again I would like to thank the authors of this very stimulating paper, I have attempted to broaden the debate by addressing the more general issues which give rise to difficulties in interpreting FDI statistics either from national data and in particular from mirror data.
